

The JET 2018-2019 Program: Isotope effects on transport and confinement in view of D-T

M. Romanelli, JET TFLs and JET contributors
JET, Culham Science Centre, UK

JET can address key physics issues for predicting and designing future tokamaks

- Largest tokamak in use and currently the only one capable of handling tritium
- ITER-like first wall (ILW): W divertor and Be walls
- Recently enhanced heating and diagnostics (including for fast particles)
- Burning plasma physics during D-T campaigns
- Isotope physics with H,D,T and mixtures

JET: $B_T=4T$, $R=2.96m$, $a=0.96m$,

$P_{NBI}=32MW$, $P_{ICRH}=12MW$

JET = D-T burning plasma + ITER-Like Wall

Challenging target for DTE2: 15MW/5s fusion power

- Plasma Wall Interaction
- ITER integrated scenarios
- **Isotope effects on T&C**
- T-cycle
 - fuelling, retention, migration, recovery, dust
- α -particle physics
- Fusion technology
 - calibration, materials under 14MeV neutrons, code validation

Disruption Mitigation Studies for ITER

Disruptions is a Challenge for ITER

- Operate ITER Disruption Mitigation Systems as on ITER
- Test ITER disruption avoidance, predictors and control
- Disruption avoidance by controlling MHD modes
- Disruption mitigation scheme with ITER-like system

JET

Installation of SPI on JET (under international collaboration)

Priorities for JET programme 2018-2020

- Objective 1: Prepare scenarios for sustained fusion performance and α -particle physics
- Objective 2: Determine the isotopes dependence of H-mode physics, SOL conditions and fuel retention
- Objective 3: Quantify the efficacy of SPI versus MGI on runaway and disruption energy dissipation and extrapolate to ITER

Other physics issues essential for the exploitation of the JET T & DT campaigns and for extrapolation to ITER

Results from last campaigns

- **L-H transition**
- **Particle transport in core and SOL**
- **Heat and momentum transport in core and SOL**
- **Global confinement**

2018-2019 JET campaigns

- **New experiments and tasks addressing isotope effects on transport and confinement**
- **Conclusion**

Results from last campaigns

- **L-H transition**
- **Particle transport in core and SOL**
- **Heat and momentum transport in core and SOL**
- **Global confinement**

2018-2019 JET campaigns

- **New experiments and tasks addressing isotope effects on transport and confinement**
- **Conclusion**

L-H threshold studies with isotopes

- For ICRH heated plasmas, threshold in H about twice D, generally consistent with most past results
- Similar to Gohil NF 2010, threshold much higher in hydrogen with more input torque
- Isotope dependence stronger in low density branch than high density branch

J. Hillesheim

L-H threshold studies with isotopes

- Largest variations observed at high and low $H/(H+D)$
- Little variation in range $0.2 < \frac{H}{(H+D)} < 0.8$
- Experiments at end of campaign with H- ^4He mixtures show drop of power threshold with helium seeding in hydrogen plasmas
 - Effect could be used during non-active phase of ITER operation

$$P_{\text{scal}} = 0.0488 \langle n_e \rangle^{0.717} B_T^{0.803} S^{0.941}$$

.... Plasma composition matters ... what is the impact of e.g. seeded impurities on L-H threshold?

J. Hillesheim

Results from last campaigns

- L-H transition
- **Particle transport in core and SOL**
- Heat and momentum transport in core and SOL
- Global confinement

2018-2019 JET campaigns

- New experiments and tasks addressing isotope effects on transport and confinement
- Conclusion

Dependence of fuelling on isotopes

NEW: systematic study of fuel transport mechanisms at SOL/edge boundary

- 3 Hz gas modulation from top of the machine
- Study the inward propagation of the electron density wave

Different GIMS lead to different edge modulation response

- For these experiments a high frequency strike point sweeping was commissioned and used for the first time
- Wiggle the legs while keeping the main plasma intact
- Use constant gas fuelling, modulate recycling

P. Lomas

New: Strike point sweeping works only in tile 5 configuration

Dependence of fuelling on isotopes

- In Hydrogen the limited NB power prevented reaching dimensionless comparison shots against Deuterium plasmas
 - Diagnostics requirement ($B_t > 1.9\text{T}$) lead to too high LH threshold
- Corner configuration was used as the main scenario since it allowed easy ne control and dimensionless scans BUT has the drawback on suboptimal SOL diagnostics and L/H transitions when sweeping
 - Limited amount of data in tile-5
- Modelling is starting to bear fruit and add to our understanding of the important phenomena
 - EDGE2D/EIRENE direct fueling is in anti-phase with gas injection suggesting transport to be the main player in plasma fueling

Analysis ongoing: the dependence of fuelling on isotopes is still not characterised. New experiment planned for 2018 (M18-24) uses experience developed to provide the necessary information

Dependence of fuelling on isotopes - pellets

M. Valovic

- Clean hydrogen plasma before pellets (no neutrons)
- At the edge $n_D/(n_D+n_H) \sim 0.35$

Dependence of fuelling on isotopes - pellets

- n_e and neutrons matched with:
 - $D_{iD} = D_{iH} = 1.5 \langle \chi_{BgB,e,i} \rangle$, $v/D = -0.4 r/a^2$, $\alpha_{crit} = 1$, $\Phi_H \sim 3 \times 10^{21}$ el/s,
 - Extra post-pellet convective loss $\tau = 50$ ms, $r/a > 0.75$, $v_0 = 7$ m/s
- Code predicts:
 - On axis $n_D/(n_D + n_H) \sim 0.33$, close to spectroscopy value
 - new situation with opposite density gradients for D and H after pellet
 - at $r/a = 0.5$ $D_{iD} \sim 0.22$ $\chi_{i,eff} \sim 0.37$ $\chi_{e,eff}$

B15-02

— (high v^*)
— (middle v^*)
— (low v^*)

ELMy H-mode in Hydrogen
H16-10

L-mode plasma

Density peaking Tritium plasma, similar or not?
2018 proposal ..and in mixed isotope plasmas?

Density peaking at different collisionalities

- W and Ni impurities are less peaked at higher ν^* in H-mode
- However, this is maybe (even probably) not due to variations in ν^* , but due to increased main ion density peaking dependence on ν^*
- Neo-classical transport probably dominates here (transport modelling on-going).

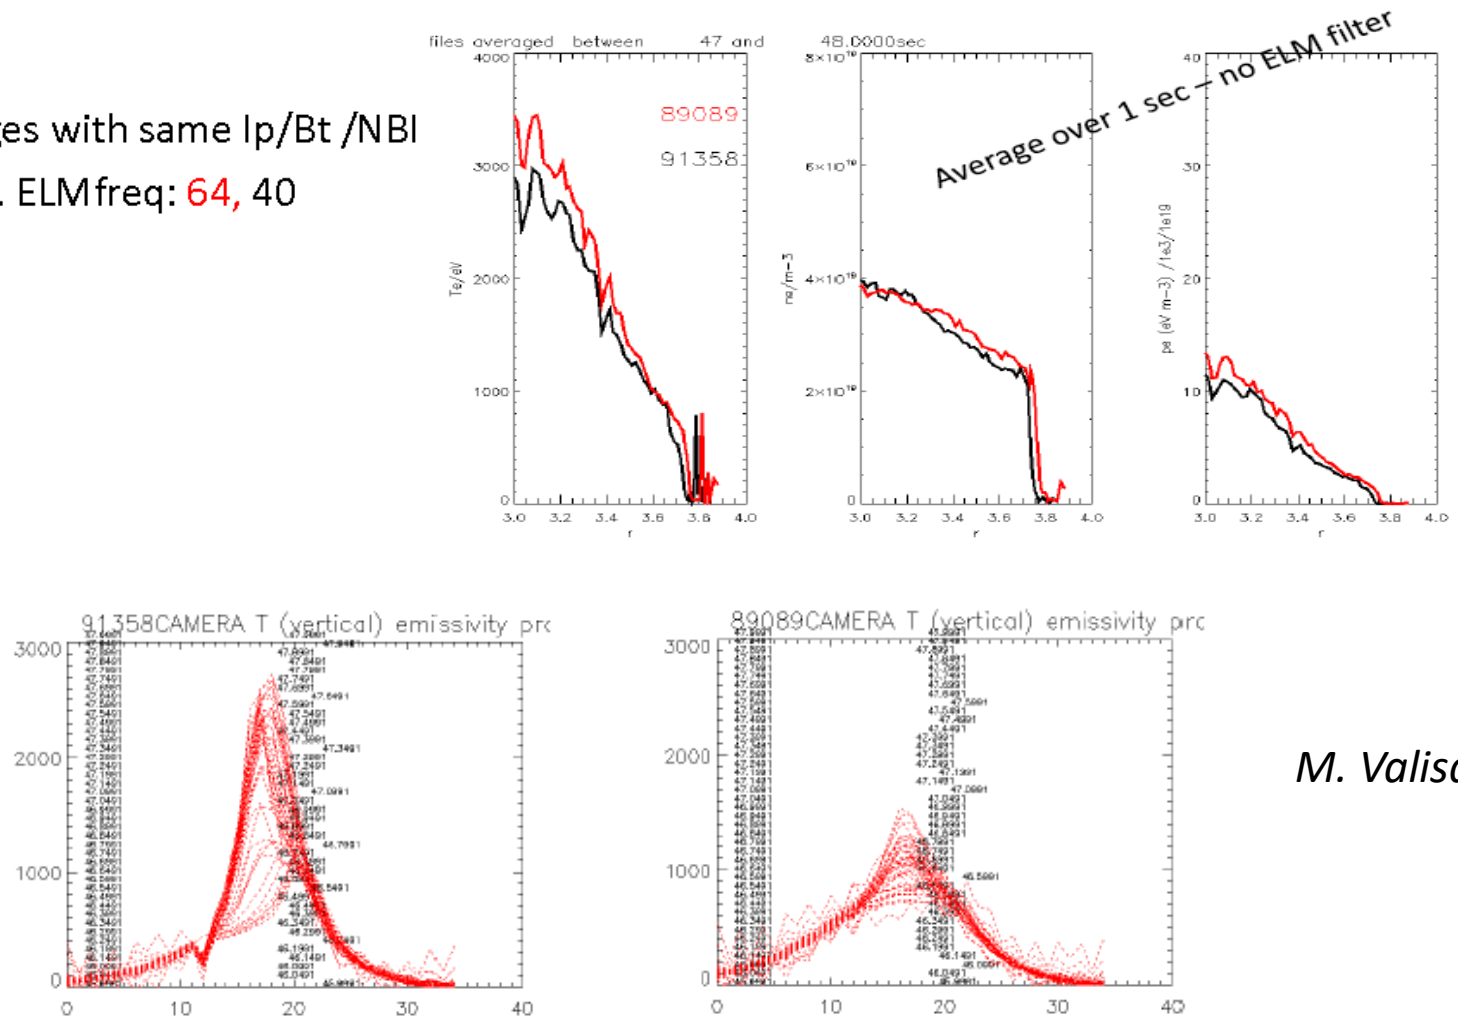

A. Czarnecka

Density peaking at different collisionalities

- Pair of discharges with same I_p/B_t /NBI and similar e-flow. ELMfreq: 64, 40

M. Valisa

Confirms previously shown indication of W to peak more in H than in D

H-mode density limit

- The density limit is not related to an inward collapse of the hot discharge core induced by overcooling of the plasma periphery by radiation.
- It was observed in D- and H-plasmas that neither detachment, nor the X-point MARFE itself, do trigger the H-L transition and that they thus do not present a limit on the plasma density.
- The DL shows a strong dependence on the isotopic mass effect, the DL is up to 35% lower in the H-plasma than in the deuterium plasma.
- The density limit in H mode on JET-ILW is nearly independent of the power

The measured Greenwald fractions are found to be consistent with the predictions from a theoretical model based on MHD instability theory in the near-SOL.

A. Huber et al., Nucl. Fusion **57** (2017)

Results from last campaigns

- L-H transition
- Particle transport in core and SOL
- **Heat and momentum transport in core and SOL**
- Global confinement

2018-2019 JET campaigns

- New experiments and tasks addressing isotope effects on transport and confinement
- Conclusion

Heat transport in D and H

Dedicated core transport studies are performed in L-mode (avoid ELM/pedestal complexity) – 3 identical L-mode plasmas have been obtained/ analysed

Ion heat flux calculated by PION . All points are consistent with gB scaling. Similar threshold values and high stiffness at 0.33 in both D and H. However, due to high stiffness, it is impossible to discriminate the mass dependence. Still, this means that R/LT_i is similar between H and D in the core, and the difference we see in the absolute value of T_i must come from edge

P. Mantica

Heat transport in D and H

With NBI we observed some ion destiffening also in H plasmas, but stabilization seems quantitatively smaller. To be investigated.

Heat transport in D and H

Te is lower already in the edge region, leading to higher R/L_{Te}

Possibly due to higher Pe_i in H (twice than in D for same parameters), which drags the electron heating to ions, with stronger ITGs which stabilize the ETGs. To be verified by GK simulations.

Different turbulence regime in Identity H and D plasmas

More experiments proposed in 2018 - 2019

Energy fluence to divertor

ELM duration most likely overestimated

Energy fluence: differences between H and D

M. Faitsch

Momentum transport – Intrinsic rotation

$B_T=2.6\text{ T}$, $I_p=2.3\text{ MA}$

Central angular frequency (rad/s) vs
 $\langle n_e \rangle$ ($10^{19}/\text{m}^3$)

$B_T=2.6\text{ T}$, $I_p=1.6\text{ MA}$

Central angular frequency (rad/s) vs
 $\langle n_e \rangle$ ($10^{19}/\text{m}^3$)

F. Nave

NB. Rotation reversals observed for $I_p=2.3\text{ MA}$. Not enough data points for conclusions at the lower I_p .

Results from last campaigns

- **L-H transition**
- **Particle transport in core and SOL**
- **Heat and momentum transport in core and SOL**
- **Global confinement**

2018-2019 JET campaigns

- **New experiments and tasks addressing isotope effects on transport and confinement**
- **Conclusion**

Isotope dependence of global confinement

- Controlled NBI power scan in **H** and **D**
- at **constant plasma density**
- Isotope purity $\geq 99\%$
- $T_i \sim T_e$

$$\tau_{th} \sim A^{0.15 \pm 0.02} P_{abs}^{-0.63 \pm 0.02}$$

$$\tau_{th} \text{ (ITER97-L)} = 0.023 I_p^{0.96} B_T^{0.03} P_{abs}^{-0.73} n_e^{0.40} A^{0.2}$$

- Isotope dependence broadly consistent with ITER97-L scaling (slightly weaker P degradation)

Positive isotope dependence of τ_{th} , in contradiction of gyro-Bohm scaling

L-mode

C. Maggi

Isotope dependence of global confinement

TRANSP power balance, with $T_i = T_e \rightarrow P_{ei} \sim n^2 (T_e - T_i) / (A T_e^{3/2}) = 0$

Isotope dependence of global confinement

- **H** and **D** pairs with **matching** profiles of dimensionless parameters: q , ρ^* , v^* , β
- B_T , $I_P \sim A^{3/4}$; then n_e and T_e should scale as : $n_e \sim A$; $T_e \sim A^{1/2}$

Pulse #	91458	89724
Isotope	H	D
Time interval [s]	17.1 – 18.9	14.0 – 16.0
B [T]	1.74	2.95
I_P [MA]	1.44	2.46
P_{loss} [MW]	2.65	6.4
$P/B^{5/3}$ [MW/ $T^{5/3}$]	1.05	1.05
τ_{th} [s]	0.155	0.19
$B \tau_{th}/A$ [Ts]	0.27	0.28

- $T_i = T_e$ in TRANSP runs (T_i and T_e very close to each other experimentally) $\rightarrow \chi_{eff}$
- Neutron yield and stored energies accurately reproduced by TRANSP
- **Dimensionless thermal diffusivities $A \chi_{eff} / B$ matched within error bars in plasma core \rightarrow confinement scale invariance principle satisfied**

L-mode

C. Maggi

Isotope dependence of global confinement

H and D at same Power
H and D at same W

Lower W_{rhhd} and W_{th}
(TRANSP) in H at same P_{NBI}

← **Lower n_e in Hydrogen**

At same injected gas rate

← **For stiff T profiles,
suggests isotope effect
originating from pedestal**

... Fast ion energy different in H and D

Isotope dependence of global confinement

- **H** and **D** pairs with **matching pre-ELM** profiles of dimensionless parameters

C. Maggi

- $B_T, I_P \sim A^{3/4}; n_e \sim A; T_e \sim A^{1/2}$
- Larger ELM losses in **H** than in **D** \longrightarrow
- ELM-averaged profiles not matched:
 $A f_{\text{ELM}} / B$ not matched **40/58** [Hz/T]
 $B \tau_{E,\text{th}} / A$ not matched **0.102/0.148** [T s]
 \rightarrow **Suggests that pedestal cannot be described by canonical plasma physics parameters only ...**

... Heat and particle sources are different
in H and D \rightarrow exp proposals

Global confinement in mixed isotopes plasmas

- Isotope ratio was scanned from $1.2 < M_{\text{eff}} < 1.8$ with similar input power (8-10MW) and gas fuelling ($\sim 1\text{e}22\text{el/s}$).
- Thermal stored energy by integrating kinetic profiles.
- Including pulses with $1.1 < M_{\text{eff}} < 1.2$ shows a more significant change.
- L-H threshold expected to be 8-9MW at full hydrogen

D. King

Results from last campaigns

- **Particle transport in core and SOL**
- **Heat and momentum transport in core and SOL**
- **Global confinement**

2018-2019 JET campaigns

- **New experiments and tasks addressing isotope effects on transport and confinement**
- **Conclusion**

2018-2019 JET experiments and tasks

- M18-13 - H/He mixtures for non-active phase of ITER operation
- M18-14 - Isotope effects on L-H transition power threshold
- M18-15 - Access to type-I ELMs with reduced torque

- Largest variations observed at high and low $H/(H+D)$
- Little variation in range $0.2 < \frac{H}{(H+D)} < 0.8$
- Experiments at end of campaign with H- ^4He mixtures show drop of power threshold with helium seeding in hydrogen plasmas
 - Effect could be used during non-active phase of ITER operation

$$P_{\text{scal}} = 0.0488 \langle n_e \rangle^{0.717} B_T^{0.803} S^{0.941}$$

J. Hillesheim

L-H transition modelling XGC

XGC results show that turbulent Reynolds-stress act in concert with neoclassical orbit loss to quench turbulent transport and form a transport barrier just inside the last closed magnetic flux surface.

Differences with isotopes and mixed species?

C. S. Chang et al, PRL 118, 175001 (2017)

Impact of neutrals on turbulence has been documented in a recent paper by Stotler

D.P. Stotler et al 2017 Nucl. Fusion 57 086028

Different isotopes have different neutral distribution due to differences in the ionization cross section. Simulations of ETB / SOL turbulence with different isotopes is crucial to understand JET results.

Neutrals & pedestal

- M18-16 - Impact of neutrals and impurities on SOL and pedestal
- M18-17 - **Power width scaling and ELM losses at high current**
- M18-18 - Determine W source including ELM, RF and isotope effects
- M18-20 - Dependence of pedestal structure on fuelling at constant beta
- T17-05 - Pedestal analysis and isotope effect
- T18-02 - **Scrape-off layer and SOL-pedestal interaction**

Modelling of SOL width with XGC

2018-2019 JET campaigns

- **New experiments and tasks addressing isotope effects on transport and confinement**
- **Conclusion**

Conclusion

- The JET 2020 program* will address key physics issues of operating with different and mixed hydrogen isotopes
- The joint US/EU exploitation of the SPI on JET will provide crucial answers to ITER for disruption control (formal agreement between EU/ITER/DOE)
- The 2019 T campaign* will provide essential information for the predictions to D-T performance and for ITER
- D-T operation in 2020* will allow to demonstrate steady fusion power in the ILW environment
- Demonstration of W control and prevention of accumulation along with fuel mix control
- Alpha physics will be uniquely addressed and we will have the chance to demonstrate alpha heating before ITER operation
- PPPL collaborators are welcome to participate in existing official collaborations (upon submission of a workplan). Any new topics of collaborations need approval from EUROfusion** (contact the JET TFLs at JET1-TFL@euro-fusion.org).

*Pending agreement on resources beyond 2018. **No JET internationalization
